## 6 Problem Set 7.1 1.) n=9, triangle indicator > Tiha, 3 nodes how many combinations of three nodes in network $\frac{9}{0} = \frac{n(n-1)(n-2)}{0} = \frac{0 \times 8 \times 7}{6} = \frac{504}{6} = \frac{84}{6}$ 84 combinations of three nodes possible in 1=9 network, therefore ting x 84 triangle indicators to check if triangle exists. 2.) global triangle = # of triangles in the retwork. triangles are powerful Structures. In this problem, we're saying that Some networth, random, named 'G', contains 84 triangles in it. That is, 3 nodes, 3 links total forming an infinite path between each other 84-triangles, each with 3 modes. 84 . 3 = 252 nodes maximum mox 6 links 15 links 3 with 5, mox 9 Max 6 nodes mox 6 links 6 mox 13 9 links mox 6 with 5 with 7, mox 15 4th 12 Max 6 nodes with 7, mox 15 4th 12 84 triangles, max 252 n triangles, min 86 min 'n' = n+2-26+1 max 'n' = n · 3 Number of triangles 'nt' min # of nodes to form int' triangles is = nt+2 max # of nodes to form int' triangles is = nt . 3 We also are told that the density is = to 1. Probability that any two nodes, chosen at random, have a link, this means that we have a complete network, quite rare.

## Problem Set 7.1 2.) ... Continued. So we know that this random network 'G' is a complete network, in which the maximum number of links are n x (n-1) We know that the number of nodes most lic between 86 and 252. In a network with 84 triangles, where every node is Connected to each other. If p=1 in a network, then there is an exact number of triangles that are formed. n=3, I triangle n=4, 4 triangles | n=5 triangles=8 | n=6 M(n-1)(n-2) > gives number of tricinates possible triangles when p=1. Process of elimination. n=10 10(9)(8) - 120 possible triangles 9(8)(7) - 84 Wow, ok, so (3) also gives us the possible number of triangles that can be formed informally meaning that p=1. So if p=1 and there are 84 triangles in this networlh, then there are 9 nodes in the network The calculations I was doing in the beginning failed to incorporate p being equal to 1.

Problem Set 7.1 A= 101000 /2 a.) Visually tues N N Mothematically: 10 A x A for [2,2) for matrix C= (101)+ (0.0)+ (101)+ (101)+ (0.0)  $A^{2}[1,1]=3$ A2[2,1]= (1.0)+ (6.1)+ (1.0)+ (1.0)+ (0.0) = 0 [23]= (1.0)+(0.1)+(1.0)+(1.1)(0.1)=1 [2,4] = 1.0+ 0.1+ 1.0+ 1.0+ 6.1=1 [2,5]=1.0+0.6+1.1+1.1+0.0=2 A3[2,2]=0.1+3.0+1.1+1.1+2.0=2 ty = 1322 - 2 - 1 triangle total -> +468 b.) Visually: [ t468 , t6810 )

Problem Set 1.1 4.) We have some random network, let's callit '6: This modern network has 10 nodes in it. This means that the most amount of triangles that this network, or any network with 10 'modes', Can have is (12) 10(9)(8)/6=120 triangles, Coincidentally, we also know that there are 120 'global' triangles in this network called '6', which means that every node in this network is connected to all other 9 nodes. Thus, there are (18) links in the network as well, being 45 links So, to recap: 6' has: · lo nodes · 45 links · 120 triangles · 8 nodes have 36 local triangles, each. We additionally know that . 8 of the nodes in this network have 36 local triangles each 36+36+36+36+36+36+36+36=188 total local triangles from the 8 nodes This means, that since every rade is linked to all other nodes, that the remaining 2 nodes must also have 36 local triangles because: -> 36.10 = 360/3=120 36x2=72 between the two The number of a lobal +36 5. We have some traveler, named John, for instance John is a frequent flier in airports who has accomulated many 'flyer miles' over the years, called having 'miles to Spend' Because of John's proffession, John con only take short-distance trips.

Problem Set 7.1 6.) We have some network, let's call it I with the following Characteristics: line network · V(L)=(1,2,3,...1)3 · n is even · how many global triangles? oglobal triangles in L since it is a line network 0-2-3-9-6-6-5-59-9 Add links->(2-4), (4-6), (6-8), (8-10) L) Now how many global triangles? Still & global thiongles

## **Problem Set: Lesson 7.1**

CDS 292. Fall, 2023

## **Instructions**

In this document you will find a set of problems intended to be answered by hand, scanned and submitted to Blackboard. Make sure your document is well organized and contains readable responses to the questions. Show your work! Full credit requires this. An answer without procedure is likely to elicit zero points. There is one addendum to this handwritten rule: any required plot can be either scanned or sent as an additional file to your submission. If you choose to submit separate files with your plots, make sure they are labeled and can be easily identified.

Note: Python code questions will occur in problem sets. The answers have to be handwritten and must respect all Python syntax rules including proper indentation of code.

**Total Points: 11** 

- 1. [1 point] How many triangle indicators do you need to check for all possible triangles in a network with n = 9?
- 2. [1 point] Network G has  $\rho = 1$ . If it contains 84 triangles (global count, i.e. T = 84), how many nodes are in the network?
- 3. Network *G* has adjacency matrix

$$\mathbf{A} = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 \end{pmatrix}$$

If the node set is  $V(G) = \{2, 4, 6, 8, 10\}$  and the rows/columns of **A** are in the same order as the nodes in V(G):

- (a) [1 point] List all triangles attached to node 4
- (b) [1 point] Find all global triangles
- 4. [2 points] In a network G, we are told that T(G) = 120 and that n = 10. In addition, we know that 8 of the nodes each has 36 local triangles. If we add them together, how many local triangles do the other two nodes have? How many local triangles do each of the two remaining nodes have? Hint: What is the maximum number of triangles in a network of n nodes?
- 5. [3 points] A frequent flyer has plenty of miles to spend. For work related reasons, this person can only take short trips, i.e. over the weekend. To maximize the number of visited airports, the optimal way to travel is to start from a destination visit two more airports and then go back

- to the first airport. This *path* describes a triangle, and therefore, we can look at the airline data to find the optimal starting airports for this traveler. To be explicit, you need to look for the airports that have the most triangles attached to them. Just as an exercise, list the 5 airports with the most triangles attached to them, with their respective  $t_i$
- 6. [2 points] L is a line network with n nodes. Assume the node set as  $V(R) = \{1, 2, 3, ..., n\}$  with n even. How many triangles (global) are in L? Now, if you add the links  $\{(2,4),(4,6),(6,8),...,(n-2,n)\}$  to the network, how many global triangles can you identify? Hint: A useful strategy to think about this problem is to create a diagram with a network using a small value for n, and then, generalize your result.
